

**CONTAINMENT PLENUM FOR LASER IRRADIATION AND REMOVAL OF
MATERIAL FROM A SURFACE OF A STRUCTURE**

Related Applications

[0001] This application claims benefit under 35 U.S.C. § 119(e) to U.S. Provisional Patent Application No. 60/456,043, filed March 18, 2003, to U.S. Provisional Patent Application No. 60/471,057, filed May 16, 2003, and to U.S. Provisional Patent Application No. 60/496,460, filed August 20, 2003, each of which is incorporated in its entirety by reference herein. This application is related to U.S. Patent Application Nos. _____ (Attorney Docket No. LOMASR.021A), _____ (Attorney Docket No. LOMASR.023A), _____ (Attorney Docket No. LOMASR.025A), _____ (Attorney Docket No. LOMASR.026A), each of which is filed on even date herewith and incorporated in its entirety by reference herein.

Statement Regarding Federally Sponsored Research or Development

[0002] This invention was funded, in part, by the Federal Emergency Management Agency as part of the Robert T. Stafford Disaster Relief and Emergency Assistance Act (42 U.S.C. § 5121 *et seq.*).

Background of the Invention

Field of the Invention

[0003] The present invention relates to the field of material processing, particularly, to an apparatus and method for drilling, cutting, and surface processing of materials using energy waves.

Description of the Related Art

[0004] Those in the wide ranging materials processing industries have long recognized the need for non-disruptive material processing. In the past, virtually all material processing, including drilling, cutting, scabbling, and the like have included numerous disruptive aspects (e.g., noise, vibration, dust, vapors, and fumes). Material processing generally includes mechanical technologies such as drilling, hammering, and other power assisted methods, and water jet based technologies. Demonstrative of the problems of material processing, U.S. Pat. No. 5,085,026 is highly illustrative. The '026 device requires

mechanical drilling of materials such as concrete or other masonry, and generates all the disruptive aspects noted above.

Summary of the Invention

[0005] In certain embodiments, a containment plenum is adapted to deliver laser light to an interaction region of an inhabitable structure to remove material from the structure. The containment plenum comprises a plenum housing adapted to be coupled to a source of laser light. The containment plenum further comprises a window substantially transparent to the laser light. The window is mounted within the plenum housing to transmit the laser light in a downstream direction and to provide a barrier to upstream transport of particulate matter generated by interaction of the laser light and the structure. The containment plenum further comprises a nozzle fluidly coupled to a source of compressed gas. The nozzle is mounted downstream of the window whereby the laser light and the compressed gas are transmitted through the nozzle in the downstream direction to the interaction region of the structure. The containment plenum further comprises a resilient interface coupled to the plenum housing and adapted to resiliently contact the structure and to substantially surround the interaction region, thereby confining the material and removing the material from the interaction region.

[0006] In certain embodiments, a containment plenum is adapted to deliver laser light to an interaction regions of an inhabitable structure to remove material from the structure. The containment plenum comprises means for coupling the containment plenum to a source of laser light. The containment plenum further comprises means for transmitting the laser light through the containment plenum in a downstream direction to the interaction region. The containment plenum further comprises means for inhibiting upstream transport of particulate matter generated by interaction of the laser light and the structure. The containment plenum further comprises means for confining the material and removing the material from the containment plenum.

[0007] In certain embodiments, a method irradiates an interaction region of an inhabitable structure with laser light to remove material from the structure. The method comprises coupling a containment plenum to a source of laser light. The method further comprises transmitting the laser light through the containment plenum in a downstream direction to the interaction region. The method further comprises inhibiting upstream

transport of particulate matter generated by interaction of the laser light and the structure. The method further comprises confining the material and removing the material from the containment plenum.

[0008] For purposes of summarizing the present invention, certain aspects, advantages and novel features of the present invention have been described herein above. It is to be understood, however, that not necessarily all such advantages may be achieved in accordance with any particular embodiment of the present invention. Thus, the present invention may be embodied or carried out in a manner that achieves or optimizes one advantage or group of advantages as taught herein without necessarily achieving other advantages as may be taught or suggested herein.

Brief Description of the Drawings

[0009] Without limiting the scope of the present invention as claimed below and referring now to the drawings and figures:

Detailed Description of the Preferred Embodiment

[0038] Reducing the disruptive aspects of material processing has long been a goal of those in materials processing industries, particularly in industries that require materials processing within or near occupied structures, such as is common in renovation and many other applications. Such long-felt needs have been particularly prevalent in seismically active areas of the earth, where there is a pressing need for an effective and economical means of retrofitting occupied structures to increase the safety of these structures.

[0039] Prior technologies are plagued by disruptive characteristics, thereby making them virtually unsuitable for retrofitting occupied structures. Additionally, such material processing technologies often present dangerous and costly “cut through” dangers. “Cut through” dangers include instances such as a worker unintentionally cutting an embedded object while drilling through the subject material. For example, a construction worker drilling a hole in an existing concrete wall may accidentally encounter reinforcing steel or rebar, or embedded utilities, such as live electrical conduit and conductors. Such an incident may result in costly damage to tools or the subject material, as well as potentially

deadly consequences (e.g., electrocution) for workers. Traditional drilling methods also can include “punch through” dangers of unexpectedly punching through the material drilled and damaging structures or personnel on the opposite side of the material.

[0040] In addition, traditional material processing equipment has been extremely burdensome to operate. Handheld power drilling and hammering devices commonly weigh in excess of fifty pounds and are often required to be held overhead by the operator for extended period of time. Conventional devices also typically produce jarring forces that the operator must absorb while holding the device. Besides the potentially injurious jarring forces, sustained heavy lifting, and “cut through” dangers, the operator and those in the vicinity of the device may be exposed to falling or projectile debris, as well as dust, fumes, vapors, vibration, and noise. This level of noisome activity is unsuitable in general for occupied structures, and is entirely unsuitable for structures used as hospitals, laboratories, and the like, where noise and vibration can be completely unacceptable.

[0041] What continues to be needed but missing from this field of art is a non-disruptive material processing technology that overcomes the drawbacks illustrated above. In certain embodiments described herein, energy waves are directed toward the surface to be processed to overcome some or all of such drawbacks. The energy waves of certain embodiments are electromagnetic waves (e.g., laser light, microwaves), while in other embodiments, they are acoustic waves (e.g., ultrasonic waves). However, in certain embodiments, such cutting units can be as bulky and often are as difficult to maneuver as their mechanical counterparts. In addition, lasers can be subject to the same “cut through” dangers as described above, wherein objects hidden within the matrix of the material to be processed can be inadvertently damaged. Lasers can also pose additional dangers of “punch through” with danger to persons or objects in the path of the laser beam. Lasers can also present complexities in removing drilled material from a cut or a drilled hole. In certain embodiments, the laser system would incorporate a remote laser generator communicating with a portable processing head that incorporates numerous non-disruptive and safety features allowing the system to be utilized within or near occupied structures.

[0042] Certain embodiments of the present invention provide fast material processing while addressing many of the shortcomings of prior technologies and allowing for

heretofore unavailable benefits (e.g., reduced disruption to activities within the structure). In certain embodiments, the method and apparatus utilize fiber connections between elements such that noisy, bulky, and heavy elements can operate at a significant distance from the actual work area. Certain embodiments are low in both noise and vibration during operation, and effectively remove dust and debris. Certain embodiments include a detection system to reduce the dangers of “cut through” or “punch through.” Certain embodiments enhance worker safety by allowing workers to be located away from the work area during material processing. Certain embodiments are separable into man-portable pieces (e.g., less than 50 pounds) to facilitate transportation to locations in proximity to or within the structure being processed by providing easy and fast portability and set-up.

[0043] Certain embodiments of the present invention provide a method and apparatus for processing fragile structures which may be damaged by conventional processing techniques. For example, using conventional saws for processing concrete grain silos as part of a retrofit or refurbishment process may result in vibrations damaging to other portions of the silo. Using a laser to process the fragile structure can reduce the collateral damage done to the structure during processing. Furthermore, certain embodiments described herein are easily assembled/disassembled, so they can be used in otherwise inaccessible portions of the structures. While embodiments described herein are disclosed in terms of processing man-made structures, in still other embodiments, the present invention can be useful for processing natural formations (e.g., as part of a mining or drilling operation).

[0044] The method and apparatus described herein represent a significant advance in the state of the art. Various embodiments of the apparatus comprise new and novel arrangements of elements and methods that are configured in unique and novel ways and which demonstrate previously unavailable but desirable capabilities. In particular, certain embodiments of the present invention provide a material processing method that is quiet, substantially vibration-free, and less likely to exude dust, debris, or noxious fumes. Additionally, certain embodiments allow a higher rate of material processing than do conventional technologies.

[0045] The detailed description set forth below in connection with the drawings is intended merely as a description of various embodiments of the present invention, and is not intended to represent the only form in which the present invention may be constructed or utilized. The description sets forth illustrated embodiments of the designs, functions, apparatus, and methods of implementing the invention. It is to be understood, however, that the same or equivalent functions and features may be accomplished by different embodiments that are also intended to be encompassed within the spirit and scope of the invention.

[0046] Figure 1 schematically illustrates an embodiment of an apparatus 50 for processing a structure having a surface. The apparatus 50 comprises a laser base unit 300, a laser manipulation system 100, and a controller 500. The laser base unit 300 is adapted to provide laser light to an interaction region and includes a laser generator 310 and a laser head 200 coupled to the laser generator 310. The laser head 200 is adapted to remove the material from the interaction region. The laser manipulation system 100 includes an anchoring mechanism 110 adapted to be releasably coupled to the structure and a positioning mechanism 121 coupled to the anchoring mechanism 110 and coupled to the laser head 200. The laser manipulation system 100 is adapted to controllably adjust the position of the laser head 200 relative to the structure. The controller 500 is electrically coupled to the laser base unit 300 and the laser manipulation system 100. The controller 500 is adapted to transmit control signals to the laser base unit 300 and to the laser manipulation system 100 in response to user input.

[0047] In certain embodiments, the laser head 200 is releasably coupled to the laser generator 310 and is releasably coupled to the positioning mechanism 121. In certain embodiments, the positioning mechanism 121 is releasably coupled to the anchoring mechanism 110, and the controller 500 is releasably coupled to the laser base unit 300 and the laser manipulation system 100. Such embodiments can provide an apparatus 50 which can be reversibly assembled and disassembled to facilitate transportation of the apparatus 50 to locations in proximity to or within the structure being processed.

Laser Base Unit

[0048] Certain embodiments of the laser base unit 300 are described below. While the laser base unit 300 is described below as comprising separate components, other

embodiments can include combinations of two or more of these components in an integral unit.

Laser Generator

[0049] Figure 2 schematically illustrates a laser base unit 300 compatible with embodiments described herein. In certain embodiments, the laser base unit 300 comprises a laser generator 310 and a cooling subsystem 320. The laser generator 310 is coupled to a power source (not shown) which provides electrical power of appropriate voltage, phase, and amperage sufficient to power the laser generator 310. The power source can also be portable in certain embodiments, and can operate without cooling water, air, or power from the facility at which the apparatus 50 is operating. Exemplary power sources include, but are not limited to, diesel-powered electric generators.

[0050] In certain embodiments, the laser generator 310 preferably comprises an arc-lamp-pumped Nd:YAG laser, but may alternatively comprise a CO₂ laser, a diode laser, a diode-pumped Nd:YAG laser, a fiber laser, or other types of laser systems. The laser generator 310 can be operated in either a pulsed mode or a continuous-wave mode. One exemplary laser generator 310 in accordance with embodiments described herein includes a Trumpf 4006D, 4000-watt, continuous-wave laser available from Trumpf Lasertechnik GmbH of Ditzingen, Germany. In other exemplary embodiments, a Yb-doped fiber laser or an Er-doped fiber laser can be used. Other types of lasers are compatible with embodiments of the present invention. Depending on the requirements unique to a given application of the method and apparatus described herein, one skilled in the art will be able to select the optimal laser for the purposes at hand.

[0051] In certain embodiments, the laser generator 310 can be located within a shipping container for ease of transport and storage. The laser generator 310 generates laser light which is preferably delivered through a glass fiber-optic cable from the laser generator 310 to the work location.

[0052] In certain alternative embodiments, the laser generator 310 comprises a gas-based CO₂ laser which generates laser light by the excitation of CO₂ gas. Such lasers provide high power output (e.g., ~ 100 W - 50 kW) at high efficiencies (e.g., ~ 5 - 13%), and are relatively inexpensive. The laser light generated by such gas-based CO₂ lasers is typically

delivered by mirrors and by using a system of ducts or arms to deliver the laser light around bends or corners.

[0053] In certain alternative embodiments, the laser generator 310 comprises a diode laser. Such diode lasers are compact compared to gas and Nd:YAG lasers so they can be used in a direct delivery configuration (e.g., in close proximity to the work site). Diode lasers provide high power (e.g., ~ 10 W - 6 kW) at high power efficiencies (e.g., ~ 25 - 40%). In certain embodiments, the laser light from a diode laser can be delivered via optical fiber, but with some corresponding losses of power.

[0054] Embodiments using a Nd:YAG laser can have certain advantages over embodiments with CO₂ lasers or diode lasers. There is long industrial experience with Nd:YAG lasers in the materials processing industry and they provide high power (e.g., ~ 100 W - 6 kW). Additionally, the laser light from a Nd:YAG laser can be delivered by optical fiber with only slight power losses (e.g., ~ 12%) through a relatively small and long optical fiber. This permits the staging of the laser generator 310 and support equipment in locations relatively far (e.g., about 100 meters) from the work area. Maintaining the laser generator 310 at a distance from the surface being processed allows the remainder of the apparatus 50 to be smaller and more portable.

[0055] Arc-lamp-pumped Nd:YAG lasers use an arc lamp to excite a Nd:YAG crystal to generate laser light. Diode-pumped Nd:YAG lasers use diode lasers to excite the Nd:YAG crystal, resulting in an increase in power efficiency (e.g., ~ 10 - 25%, as compared to less than 5% for arc-lamp-pumped Nd:YAG lasers). This increased efficiency results in the diode-pumped laser having a better beam quality, and requiring a smaller cooling subsystem 320. An exemplary arc-lamp-pumped Nd:YAG laser is available from Trumpf Lasertechnik GmbH of Ditzingen, Germany.

[0056] Typically, the generation of laser light by the laser generator 310 creates excess heat which is preferably removed from the laser generator 310 by the cooling subsystem 320 coupled to the laser generator 310. The amount of cooling needed is determined by the size and type of laser used, but can be about 190 kW of cooling capacity. The cooling subsystem 320 can utilize excess cooling capability at a job site, such as an existing process water or chilled water cooling subsystem. Alternatively, a unitary cooling

subsystem 320 dedicated to the laser generator 310 is preferably used. Unitary cooling subsystems 320 may be air- or liquid-cooled.

[0057] In certain embodiments, as schematically illustrated in Figure 2, the cooling subsystem 320 comprises a heat exchanger 322 and a water chiller 324 coupled to the laser 310 to provide sufficient circulatory cooling water to the laser generator 310 to remove the excess heat. The heat exchanger 322 preferably removes a portion of the excess heat from the water, and circulates the water back to the water chiller 324. The water chiller 324 cools the water to a predetermined temperature and returns the cooling water to the laser generator 310. Exemplary heat exchangers 322 and water coolers 324 in accordance with embodiments described herein are available from Trumpf Lasertechnik GmbH of Ditzingen, Germany.

Laser Head

[0058] In certain embodiments, the laser head 200 is coupled to the laser generator 310 and serves as the interface between the apparatus 50 and the structure being irradiated. As schematically illustrated by Figure 1, an energy conduit 400 couples the laser head 200 and the laser generator 310 and facilitates the transmission of energy from the laser generator 310 to the laser head 200. In certain embodiments, the energy conduit 400 comprises an optical fiber which transmits laser light from the laser generator 310 to the laser head 200. In other embodiments, the energy conduit 400 comprises conductors that may include fiber-optic, power, or control wiring cables.

[0059] Figure 3A schematically illustrates a laser head 200 in accordance with embodiments described herein. The laser head 200 comprises a connector 210, at least one optical element 220, a housing 230, and a containment plenum 240. In certain embodiments, the connector 210 is coupled to the housing 230, is optically coupled to the laser generator 310 via the energy conduit 400, and is adapted to transmit laser light from the laser generator 310. The optical element 220 can be located within the connector 210, the housing 230, or the containment plenum 240. Figure 3A illustrates an embodiment in which the optical element 220 is within the housing 230. In embodiments in which the conduit 400 provides laser light to the laser head 200, the laser light is transmitted through the optical element 220 prior to impinging on the structure being irradiated.

[0060] Figure 3B schematically illustrates one configuration of a laser head 200 in accordance with embodiments described herein. The housing 230 comprises a distal portion 232, an angle portion 234, and a proximal portion 236. As used herein, the terms “distal” and “proximal” have their standard definitions, referring generally to the position of the portion relative to the interaction region. The connector 210 is coupled to the distal portion 232, which is coupled to the angle portion 234, which is coupled to the proximal portion 236, which is coupled to the containment plenum 240. Configurations such as that illustrated by Figure 3B can be used for drilling and scabbling the surface of the structure (e.g., concrete wall). Various components of the laser head 200 are available from Laser Mechanisms, Inc. of Farmington Hills, Michigan.

[0061] In certain embodiments in which the energy conduit 400 comprises an optical fiber, the connector 210 receives laser light transmitted from the laser generator 310 through the optical fiber to the laser head 200. In certain such embodiments, the connector 210 comprises a lens 212 which collimates the diverging laser light emitted by the conduit 400. The lens 212 can comprise various materials which are transmissive and will refract the laser light in a desired amount. Such materials include, but are not limited to, borosilicate crown glass (BK7), quartz (SiO_2), zinc selenide (ZnSe), and sodium chloride (NaCl). The material of the lens 212 can be selected based on the quality, cost, and stability of the material. Borosilicate crown glass is commonly used for transmissive optics with Nd:YAG lasers, and zinc selenide is commonly used for transmissive optics with CO_2 lasers.

[0062] The lens 212 can be mounted in a removable assembly in certain embodiments to facilitate cleaning, maintenance, and replacement of the lens 212. In addition, the mounting of the lens 212 can be adjustable (e.g., using thumbscrews or Allen hex screws) so as to optimize the alignment and focus of the light beam. In certain embodiments, the lens 212 can provide additional modification of the beam profile (e.g., focussing, beam shape).

[0063] The collimated laser light of certain embodiments is then transmitted through the laser head 200 via other optical elements within the laser head 200. In certain embodiments, the distal portion 232 comprises a generally straight first tube through which laser light propagates to the angle portion 234, and the proximal portion 236 comprises a

generally straight second tube through which the laser light from the angle portion 234 propagates. In certain embodiments, the distal portion 232 contains a lens 233, and the angle portion 234 contains a mirror 235 which directs the light through the proximal portion 236 and the containment plenum 240 onto the structure. In other embodiments, other devices (e.g., a prism) can be used in the angle portion 234 to direct the light through the proximal portion 236 and the containment plenum 240 onto the structure.

[0064] The lens 233 can be mounted in a removable assembly in certain embodiments to facilitate cleaning, maintenance, and replacement of the lens 233. In addition, the mounting of the lens 233 can be adjustable (e.g., using thumbscrews or Allen hex screws) so as to optimize the alignment and focus of the light beam. In certain embodiments, the lens 233 focuses the light received from the lens 212, while in other embodiments, the lens 233 can provide additional modification of the beam profile (e.g., beam shape). Exemplary lenses 233 include, but are not limited to, a 600-mm focal length silica plano-convex lens (e.g., Part No. PLCX-50.8-309.1-UV-1064 available from CVI Laser Corp. of Albuquerque, New Mexico). The lens 233 can comprise various materials which are transmissive and will refract the laser light in a desired amount. Such materials include, but are not limited to, borosilicate crown glass, quartz, zinc selenide, and sodium chloride. Exemplary lens mounting assemblies include, but are not limited to, Part Nos. PLALH0097 and PLFLH0119 available from Laser Mechanisms, Inc. of Farmington Hills, Michigan.

[0065] In the embodiment schematically illustrated by Figure 3B in which the distal portion 232 is substantially perpendicular to the proximal portion 236, the mirror 235 reflects the light through an angle of approximately 90 degrees. Other embodiments are configured to reflect the light through other angles. The mirror 235 can be mounted on a removable assembly in certain embodiments to facilitate cleaning, maintenance, and replacement of the mirror 235. In addition, the mounting of the mirror 235 can be adjustable (e.g., using thumbscrews or Allen hex screws) so as to optimize the alignment and focus of the light beam. In certain embodiments, the mirror 235 can also have a curvature or otherwise be configured so as to focus the light beam or otherwise modify the beam profile (e.g., beam shape). Exemplary mirrors 235 include, but are not limited to, metal mirrors such as copper mirrors (e.g., Part Nos. PLTRG19 and PLTRC0024 from Laser Mechanisms, Inc.

of Farmington Hills, Michigan), and gold-coated copper mirrors (e.g., Part No. PLTRC0100 from Laser Mechanisms, Inc.). In other embodiments, dielectric-coated mirrors can be used.

[0066] Figure 3C schematically illustrates another configuration of a laser head 200 in accordance with embodiments described herein. The housing 230 comprises the distal portion 232, a first angle portion 234, a second angle portion 234', and the proximal portion 236. The connector 210 is coupled to the distal portion 232, which is coupled to the first angle portion 234, which is coupled to the second angle portion 234', which is coupled to the proximal portion 236, which is coupled to the containment plenum 240. Configurations such as that illustrated by Figure 3C can be used for cutting the structure in spatially constrained regions (e.g., cutting off portions of a concrete wall near a corner or protrusion).

[0067] As described above, in certain embodiments, the connector 210 comprises a lens 212 and the distal portion 232 is tubular and contains a lens 233. The first angle portion 234 of the embodiment illustrated by Figure 3C contains a first mirror 235 which directs the light to the second angle portion 234' which contains a second mirror 235'. The second mirror 235' directs the light through the proximal portion 236, which can be tubular, and through the containment plenum 240 onto the structure.

[0068] In the embodiment schematically illustrated by Figure 3C, the first mirror 235 reflects the light through an angle of approximately 90 degrees and the second mirror 235' reflects the light through an angle of approximately -90 degrees such that the proximal portion 236 is substantially parallel to the distal portion 232. In such embodiments, the light emitted by the containment plenum 240 is substantially parallel to, but displaced from, the light propagating through the distal portion 232. Other embodiments have the first mirror 235 and the second mirror 235' configured to reflect the light through other angles. Certain embodiments comprise a straight tubular portion between the first angle portion 234 and the second angle portion 234' to provide additional displacement of the light emitted by the containment plenum 240 from the light propagating through the distal portion 232.

[0069] In certain embodiments, the coupling between the distal portion 232 and the first angle portion 234 is rotatable. In certain other embodiments, the coupling between the first angle portion 234 and the second angle portion 234' is rotatable. These rotatable couplings can comprise swivel joints which can be locked in position by thumbscrews. Such

embodiments provide additional flexibility in directing the light emitted by the containment plenum 240 in a selected direction. In certain embodiments, the selected direction is non-planar with the light propagating through the distal portion 232.

[0070] As described above, one or both of the first mirror 235 and the second mirror 235' can be mounted on a removable assembly in certain embodiments to facilitate cleaning, maintenance, and replacement. In addition, the mountings of the first mirror 235 and/or the second mirror 235' can be adjustable (e.g., using thumbscrews or Allen hex screws) so as to optimize the alignment and focus of the light beam. In certain embodiments, one or both of the first mirror 235 and the second mirror 235' can also have a curvature or otherwise be configured so as to focus the light beam or otherwise modify the beam profile (e.g., beam shape).

[0071] In certain embodiments, one or more of the optical elements 220 within the laser head 200 (e.g., lens 212, lens 233, mirror 235, mirror 235') are water-cooled or air-cooled. Cooling water can be supplied by a heat exchanger located near the laser head 200 and dedicated to providing sufficient water flow to the laser head 200. In certain such embodiments, the conduits for the cooling water for each of the optical elements 220 can be connected in series so that the cooling water flows sequentially in proximity to the optical elements 220. In other embodiments, the conduits are connected in parallel so that separate portions of the cooling water flow in proximity to the various optical elements 220. Exemplary heat exchangers include, but are not limited to a Miller Coolmate™ 4, available from Miller Electric Manufacturing Co. of Appleton, Wisconsin. The flow rate of the cooling water is preferably at least approximately 0.5 gallons per minute.

[0072] In certain embodiments, the laser head 200 comprises a containment plenum 240 coupled to the proximal portion 236 and which interfaces with the structure. In certain embodiments, the containment plenum 240 is adapted to confine material (e.g., debris and fumes generated during laser processing) removed from the structure and remove the material from the interaction region. The containment plenum 240 can also be further adapted to reduce noise and light emitted from the interaction region out of the containment plenum 240 (e.g., into the nominal hazard zone ("NHZ") of the laser). One goal of the containment plenum 240 can be to ensure that no laser radiation in excess of the accessible

emission limit (“AEL”) or maximum-permissible exposure (“MPE”) limit reaches the eye or skin of any personnel.

[0073] Figure 4 schematically illustrates a cross-sectional view of a containment plenum 240 in accordance with embodiments described herein. The containment plenum 240 of Figure 4 comprises a plenum housing 242, a window 243, a nozzle 244, a resilient interface 246, an extraction port 248, and a compressed gas inlet 249. The plenum housing 242 can be coupled to a source of laser light (e.g., the proximal portion 236 of the laser head 200) and can provide structural support for the other components of the containment plenum 240. Exemplary materials for the plenum housing 242 include, but are not limited to, metals (e.g., aluminum, steel) which can be in the form of thin flexible sheets, ceramic materials, glass or graphite fibers, and fabric made from glass or graphite fibers. In certain embodiments, the plenum housing 242 is either air-cooled or water-cooled to reduce heating of the plenum housing 242. Coolant conduits for the plenum housing 242 can be coupled in series or in parallel with the coolant conduits for other components of the laser head 200.

[0074] The window 243 can be positioned upstream of the nozzle 244 and within the propagation path of the laser light from the proximal portion 236 to the structure. As used herein, the terms “downstream” and “upstream” have their ordinary meanings referring to the propagation direction of the laser light and to the direction opposite to the propagation direction of the laser light, respectively. In such embodiments, the light propagating through the containment plenum 240 reaches the window 243 prior to reaching the nozzle 244. In such embodiments in which the light propagates downstream through the window 243, the window 243 is substantially transparent to the laser light. The window 243 can be mounted within the plenum housing 242 to transmit the laser light in the downstream direction. Exemplary windows 243 include, but are not limited to, a silica window (e.g., Part No. W2-PW-2037-UV-1064-0 available from CVI Laser Corp. of Albuquerque, New Mexico).

[0075] Dust and/or dirt on the optical elements of the laser head 200 can absorb an appreciable fraction of the laser light, resulting in nonuniform heating which can damage the optical elements. In certain embodiments, the window 243 is mounted within the plenum housing 242 to provide a barrier to the upstream transport of dust, smoke, or other particulate matter generated by the interaction of the laser light and the structure. In this way, the

window 243 can facilitate protection of the upstream optical elements within the other portions of the laser head 200.

[0076] The window 243 can be mounted in a removable assembly in certain embodiments to facilitate cleaning, maintenance, and replacement of the window 243. In certain embodiments, the window 243 focuses the light received from the proximal portion 236, while in other embodiments, the window 243 can provide additional modification of the beam profile (e.g., beam shape). In such embodiments, the mounting of the window 243 can be adjustable (e.g., using thumbscrews or Allen hex screws) so as to optimize the alignment and focus of the light beam. Exemplary window mounting assemblies include, but are not limited to, Part Nos. PLALH0097 and PLFLH0119 available from Laser Mechanisms, Inc. of Farmington Hills, Michigan. In certain embodiments, the window 243 is either air-cooled or water-cooled.

[0077] The laser light transmitted through the window 243 is emitted through the nozzle 244 towards the interaction region of the structure. The laser light can be focussed near the opening of the nozzle 244. Exemplary materials for the nozzle 244 include, but are not limited to metals (e.g., copper). In certain embodiments, the nozzle 244 is either air-cooled or water-cooled to reduce heating of the nozzle 244. Coolant conduits for the nozzle 244 can be coupled in series or in parallel with the coolant conduits for other components of the laser head 200.

[0078] The laser light propagating through the nozzle 244 preferably does not impinge the nozzle 244 (termed “clipping”) to avoid excessively heating and damaging the nozzle 244. Improper alignment of the laser light through the laser head 200 can cause clipping. The opening of the nozzle 244 can be sufficiently large so that the laser light does not appreciably interact with the nozzle 244. In certain embodiments, the nozzle 244 is approximately 0.3 inches in diameter.

[0079] In certain embodiments, the resilient interface 246 of the containment plenum 240 is adapted to contact the structure and to substantially surround the interaction region, thereby facilitating confinement and removal of material from the interaction region. In addition, the resilient interface 246 can facilitate blocking light and/or sound from

escaping outside the containment plenum 240. Exemplary resilient interfaces 246 include, but are not limited to, a wire brush.

[0080] In certain embodiments, the extraction port 248 of the containment plenum 240 is adapted to extract an appreciable portion of the material (e.g., gas, vapor, dust, and debris) generated within the interaction region during operation. The extraction port 248 can be coupled to a vacuum generator (not shown) which creates a vacuum to pull material (e.g., airborne particulates, gases, and vapors) from the interaction region. In this way, the extraction port 248 can provide a pathway for removal of the material from the containment plenum 240.

[0081] In certain embodiments, the compressed gas inlet 249 is adapted to provide compressed gas (e.g., air) to the containment plenum 240. In certain embodiments, the compressed gas inlet 249 is fluidly coupled to the nozzle 244 which is adapted to direct a compressed gas stream to the interaction region. In certain embodiments, compressed gas flows coaxially with the laser light through the nozzle 244. The window 243 of certain embodiments provides a surface against which the compressed gas exerts pressure. In this way, the compressed gas can flow through the nozzle 244 to the interaction region at a selected pressure and velocity.

[0082] The compressed gas flowing from the compressed gas inlet 249 through the nozzle 244 can be used to deter dust, debris, smoke, and other particulate matter from entering the nozzle 244. In this way, the compressed gas can facilitate protection of the window 243 from such particulate matter. In addition, the compressed gas can be directed by the nozzle 244 to the interaction region so as to facilitate removal of material from the interaction region. The nozzle 244 can be used in this manner in embodiments in which the structure includes concrete with a high percentage of Si, so that the resultant glassy slag is sufficiently viscous and more difficult to remove from the interaction region.

[0083] In certain embodiments, the compressed air is substantially free of oil, moisture, or other contaminants to avoid contaminating the surface of the window 243 and potentially damaging the window 243 by nonuniform heating. An exemplary source of instrument quality ("IQ") compressed air is the 300-IQ air compressor available from Ingersoll-Rand Air Solutions Group of Davidson, North Carolina. The source of compressed

air preferably provides air at a sufficient flow rate determined in part by the length of the hose delivering the air, and the number of components using the air and their requirements.

[0084] In certain embodiments, the air compressor can be located hundreds of feet away from the laser head 200. In such embodiments, the source of compressed air can comprise an air dryer to reduce the amount of moisture condensing in the air conduits or hoses between the air compressor and the laser head 200. An exemplary air dryer in accordance with embodiments described herein is the 400 HSB air dryer available from Zeks Compressed Air Solutions of West Chester, Pennsylvania.

[0085] In certain embodiments, as schematically illustrated in Figure 5, the laser head 200 comprises a sensor 250 adapted to measure the relative distance between the laser head 200 and the interaction region. Figure 5 schematically illustrates an embodiment in which the containment plenum 240 comprises the sensor 250, although other locations of the sensor 250 are also compatible with embodiments described herein. As material is removed from the structure, the interaction region extends into the structure. The sensor 250 then provides a measure of the depth of the interaction region from the surface of the structure. The sensor 250 can use various technologies to determine this distance, including, but not limited to, acoustic sensors, infrared sensors, tactile sensors, and imaging sensors. In certain embodiments in which laser scabbling or machining is performed, a sensor 250 comprising a diode laser and utilizing triangulation could be used to determine the distance between the laser head 200 and the surface being processed. Such a sensor 250 can also provide a measure of the amount of material removed from the surface.

[0086] In certain embodiments, the sensor 250 is coupled to the controller 500, and the controller 500 is adapted to transmit control signals to the laser base unit 300 in response to signals from the sensor 250. The laser base unit 300 can be adapted to adjust one or more parameters of the laser light in response to the control signals. In this way, the depth information from the sensor 250 can be used in real-time to adjust the focus or other parameters of the laser light.

[0087] In other embodiments, the controller 500 is adapted to transmit control signals to the laser manipulation system 100 in response to signals from the sensor 250. The laser manipulation system 100 is adapted to adjust the relative distance between the laser

head 200 and the interaction region in response to the control signals. In addition, the laser manipulation system 100 can be adapted to adjust the position of the laser head 200 along the surface of the structure in response to the control signals. In this way, the depth information from the sensor 250 at a first location can be used in real-time to move the laser light to another location along the surface once a desired depth at the first location is achieved.

[0088] In other embodiments, the sensor 250 is used in conjunction with statistical methods to determine the depth of the interaction region. In such embodiments, the sensor 250 is first used in a measurement phase to develop statistical data which correlates penetration depths with certain processing parameters (e.g., material being processed, light intensity). During the measurement phase, selected processing parameters are systematically varied for processing a test or sample surfaces indicative of the surfaces of the structure to be processed. The sensor 250 is used in the measurement phase to determine the depth of the interaction region corresponding to these processing parameters. In certain such embodiments, the sensor 250 can be separate from the laser head 200, and can be used during the processing of the structure or during periods when the processing has been temporarily halted in order to measure the depth of the interaction region. Exemplary sensors 250 compatible with such embodiments include, but are not limited to, calipers or other manual measuring devices which are inserted into the resultant hole to determine the depth of the interaction region.

[0089] In certain embodiments, the controller 500 contains this resulting statistical data regarding the correlation between the processing parameters and the depth of the interaction region. During a subsequent processing phase, the structure is processed, but rather than using the sensor 250 at this time, the controller 500 can be adapted to determine the relative distance by accessing the statistical data corresponding to the particular processing parameters being used. Such an approach represents a reliable and cost-effective approach for determining the depth of the interaction region while processing the structure.

[0090] In alternative embodiments, the sensor 250 is adapted to provide a measure of the distance between the laser head 200 and the surface of the structure. In such embodiments, the sensor 250 can be adapted to provide a fail condition signal to the controller 500 upon detection of the relative distance between the laser head 200 and the

structure exceeding a predetermined distance. Such a fail condition may result from the apparatus 50 inadvertently becoming detached from the structure. The controller 500 can be adapted to respond to the fail condition signal by sending appropriate signals to the laser base unit 300 to halt the transmission of energy between the laser base unit 300 and the laser head 200. In certain embodiments, the transmission is preferably halted when the laser head 200 is further than one centimeter from the surface of the structure. In this way, the apparatus 50 can utilize the sensor 250 to insure that laser light is not emitted unless the containment plenum 240 is in contact with the structure. In certain embodiments, the sensor 250 comprises a proximity switch which contacts the surface of the structure while the apparatus 50 is attached to the structure.

Laser Manipulation System

[0091] In certain embodiments, the laser manipulation system 100 serves to accurately and repeatedly position the laser head 200 in relation to the structure so as to provide articulated robotic motion generally parallel to the surface to be processed. To do so, the laser manipulation system 100 can be releasably affixed to the structure to be processed, and can then accurately move the laser head 200 in proximity to that surface. Figures 6A and 6B schematically illustrate two opposite elevated perspectives of an embodiment in which the laser manipulation system 100 comprises an anchoring mechanism 110 adapted to be releasably coupled to the structure and a positioning mechanism 121 coupled to the anchoring mechanism 110 and coupled to the laser head 200. In certain embodiments, the laser manipulation system 100 can be advantageously disassembled and reassembled for transport, storage, or maintenance.

Anchoring Mechanism

[0092] Certain embodiments of the laser manipulation system 100 comprise an anchoring mechanism 110 to releasably affix the laser manipulation system 100 to the structure to be processed. The anchoring mechanism 110 can be adapted to be releasably coupled to the structure and can comprise one or more attachment interfaces 111.

[0093] In the embodiment schematically illustrated in Figure 6B, the anchoring mechanism 110 comprises a pair of attachment interfaces 111. Each attachment interface 111 comprises at least one resilient vacuum pad 112, at least one interface mounting device

114, at least one vacuum conduit 116, at least one mounting connector 118, and a coupler 119 adapted to couple the attachment interface 111 of the anchoring mechanism 110 to the positioning mechanism 121. While the embodiment schematically illustrated in Figures 6A and 6B have two vacuum pads 112 for each of the two attachment interfaces 111, other embodiments utilize any configuration or number of attachment interfaces 111 and vacuum pads 112.

[0094] In the embodiment illustrated by Figure 7, two vacuum pads 112 are coupled to the interface mounting device 114. In certain embodiments, each vacuum pad 112 comprises a circular rubber pad which forms an effectively air-tight region when placed on the structure. Each vacuum pad 112 is fluidly coupled to at least one vacuum generator (not shown) via a vacuum conduit 116 (e.g., a flexible hose). The vacuum generator may use fluid power (e.g., compressed air) to generate the vacuum, or it may use an external vacuum source. The vacuum generator draws air out from the air-tight region between the vacuum pad 112 and the structure via the vacuum conduit 116, thereby creating a vacuum within the air-tight region. Atmospheric pressure provides a force which reversibly affixes the vacuum pad 112 to the structure.

[0095] The interface mounting device 114 comprises a rigid metal support upon which is mounted the vacuum pads 112, the mounting connector 118, and the coupler 119. In certain embodiments, the mounting connector 118 can comprise a ground-based support connector 118a adapted to be releasably attached to a ground-based support system 700, as described more fully below. In other embodiments, the mounting connector 118 can comprise at least one suspension-based support connector 118b adapted to be releasably attached to a suspension-based support system 800, as described more fully below. The coupler 119 is adapted to releasably couple the interface mounting device 114 to the positioning mechanism 121. In certain embodiments, the coupler 119 comprises at least one protrusion which is connectable to at least one corresponding recess in the positioning mechanism 121.

[0096] In alternative embodiments, the anchoring mechanism 110 can comprise other technologies for anchoring the apparatus 50 to the structure to be processed. These other technologies include, but are not limited to, a winch, suction devices (e.g., cups,

gekkomats, or skirts) affixed to the apparatus 50 or on quasi-tank treads, mobile scaffolding suspended from the structure, and a rigid ladder. These technologies can also be used in combination with one another in certain embodiments of the anchoring mechanism 110.

Positioning Mechanism

[0097] Certain embodiments of the laser manipulation system 100 comprise a positioning mechanism 121 to accurately move the laser head 200 while in proximity to the structure to be processed. Figure 8 schematically illustrates an exploded view of one embodiment of the positioning mechanism 121 along with the attachment interfaces 111 of the anchoring mechanism 110. The positioning mechanism 121 of Figure 8 comprises a first-axis position system 130, a second-axis position system 150, an interface 140, and a laser head receiver 220. The first-axis position system 130 is releasably coupled to the attachment interfaces 111 of the anchoring mechanism 110 by at least one coupler 132. The interface 140 (comprising a first piece 140a and a second piece 140b in the embodiment of Figure 8) releasably couples the second-axis position system 150 to the first-axis position system 130. The laser head receiver 220 is releasably coupled to the second-axis position system 150, and is adapted to be releasably coupled to the housing 230 of the laser head 200.

[0098] In certain embodiments, the first-axis position system 130 comprises at least one coupler 132 having a recess which is releasably connectable to at least one corresponding protrusion of the coupler 119 of the anchoring mechanism 110. Such embodiments are advantageously disassembled and reassembled for transport, storage, or maintenance of the positioning mechanism 121. Other embodiments can have the first-axis position system 130 fixedly coupled to the anchoring mechanism 110.

[0099] In certain embodiments, the first-axis position system 130 moves the laser head 200 in a first direction substantially parallel to the surface of the structure. In the embodiment schematically illustrated by Figure 9, the first-axis position system 130 further comprises a first rail 134, a first drive 136, and a first stage 138. The first stage 138 is movably coupled to the first rail 134 under the influence of the first drive 136. The first piece 140a of the interface 140 is fixedly coupled to the first stage 138 so that the first drive 136 can be used to move the interface 140 along the first rail 134. In certain embodiments, the first-axis position system 130 further comprises sensors, limit switches, or other devices

which provide information regarding the position of the first stage 138 along the first rail 134. This information can be provided to the controller 500, which is adapted to transmit control signals to the first drive 136 or other components of the laser manipulation system 100 in response to this information.

[0100] Exemplary first drives 136 include, but are not limited to, hydraulic drives, pneumatic drives, electromechanical drives, screw drives, and belt drives. First rails 134, first drives 136, and first stages 138 compatible with embodiments described herein are available from Tol-O-Matic, Inc. of Hamel, Minnesota. Other types and configurations of first rails 134, first drives 136, and first stages 138 are also compatible with embodiments described herein.

[0101] In certain embodiments, the second-axis position system 150 moves the laser head 200 in a second direction substantially parallel to the surface of the structure. The second direction in certain embodiments is substantially perpendicular to the first direction of the first-axis position system 130. In the embodiment schematically illustrated by Figure 10, the second-axis position system 150 comprises a second rail 152, a second drive 154, and a second stage 156. In certain embodiments, the first-axis position system 130 and the second-axis position system 150 provide linear movements of the laser head 200. In other embodiments, the first-axis position system 130 and the second-axis position system 150 provide circular and axial movements of the laser head 200, respectively.

[0102] In certain embodiments, the second stage 156 is movably coupled to the second rail 152 under the influence of the second drive 154. The laser head receiver 220 is releasably coupled to the second stage 156 so that the second drive 154 can be used to move the laser head receiver 220 along the second rail 152. In certain embodiments, the second-axis position system 150 further comprises sensors, limit switches, or other devices which provide information regarding the position of the second stage 156 along the second rail 152. This information can be provided to the controller 500, which is adapted to transmit control signals to the second drive 154 or other components of the laser manipulation system 100 in response to this information.

[0103] Exemplary second drives 154 include, but are not limited to, hydraulic drives, pneumatic drives, electromechanical drives, screw drives, and belt drives. Second

rails 152, second drives 154, and second stages 156 compatible with embodiments described herein are available from Tol-O-Matic, Inc. of Hamel, Minnesota. Other types and configurations of second rails 152, second drives 154, and second stages 156 are also compatible with embodiments described herein.

[0104] In certain embodiments, the second rail 152 is fixedly coupled to the second piece 140b of the interface 140. The second piece 140b can comprise at least one recess which is releasably connectable to at least one corresponding protrusion of the first piece 140a of the interface 140. Such embodiments are advantageously disassembled and reassembled for transport, storage, or maintenance of the positioning mechanism 121. In other embodiments, the interface 140 can be made of a single piece which is releasably coupled to one or both of the first stage 138 and the second rail 152. Other embodiments are not configured for convenient disassembly (e.g., having an interface 140 made of a single piece and that is fixedly coupled to both the first stage 138 and the second rail 152).

[0105] In certain embodiments, the interface 140 comprises a tilt mechanism 144 to adjust the relative orientation between the first rail 134 and the second rail 152. As schematically illustrated in Figure 11A, the first piece 140a of the interface 140 is coupled to the first stage 138 on the first rail 134, and comprises a pair of protuberances 142 adapted to couple with corresponding recesses of the second piece 140b of the interface 140. The tilt mechanism 144 comprises a first plate 145, a hinge 146, a second plate 147, and a pair of support braces 148. The first plate 145 is fixedly mounted to the first stage 138 and is substantially parallel to the surface upon which the anchoring mechanism 110 is mounted. The second plate 147 is pivotally coupled to the first plate 145 by the hinge 146, and can be locked in place by the support braces 148.

[0106] In Figure 11A, the tilt mechanism 144 is configured so that the first plate 145 and the second plate 147 are substantially parallel to one another. In this configuration, the plane of movement defined by the first direction and the second direction of the laser head 200 is substantially parallel to the surface upon which the anchoring mechanism 110 is coupled. In Figure 11B, the tilt mechanism 144 is configured so that the second plate 147 is at a non-zero angle (e.g., 90 degrees) relative to the first plate 145. In this configuration, the plane of movement defined by the first direction and the second direction of the laser head

200 is at a non-zero angle relative to the surface upon which the anchoring mechanism 110 is coupled.

[0107] In certain embodiments, the laser head receiver 220 is releasably coupled the housing 230 of the laser head 200. Figure 12 schematically illustrates a laser head receiver 220 compatible with embodiments described herein. The laser head receiver 220 is coupled to the second stage 156 and comprises a releasable clamp 222 and a third-axis position system 224. The clamp 222 is adapted to hold the housing 230 of the laser head 200. The third-axis position system 224 is adapted to adjust the relative distance between the laser head 200 and the structure being processed. In certain embodiments, the third-axis position system 224 comprises a screw drive which moves the clamp 222 substantially perpendicularly to the second rail 152. In certain embodiments, as schematically illustrated by Figure 12, the screw drive is manually actuated by a handle 226, which can be rotated to move the clamp 222. In other embodiments, the screw drive is automatically controlled by equipment responsive to control signals from the controller 500.

Ground-Based Support System

[0108] In certain embodiments, the apparatus 50 can be utilized with a ground-based support system 700 which is releasably coupled to the apparatus 50. The interface mounting devices 114 can each comprise a ground-based support connector 118a adapted to releasably couple to the ground-based support system 700. The ground-based support system 700 advantageously attaches to various types of external boom systems, such as commercially-available lifting- or positioning-type systems, which can support some of the weight of the apparatus 50, thereby reducing the weight load supported by the anchoring mechanism 110. The ground-based support system 700 can be used to facilitate use of the apparatus 50 on substantially vertical surfaces (e.g., walls) or on substantially horizontal surfaces (e.g., ceilings).

[0109] In certain embodiments, the ground-based support system 700 includes a support structure 710 such as that schematically illustrated in Figure 13. The support structure 710 of Figure 13 comprises a boom connector 712, a rotational mount 714, a spreader member 716, a pair of primary posts 718, and a pair of auxiliary posts 720. The boom connector 712 is adapted to attach to a selected external boom system. The rotational

mount 714 is adapted to be rotatably coupled to the boom connector 712 and fixedly coupled to the spreader member 716 so that the boom connector 712 can be advantageously rotated relative to the support structure 710.

[0110] The primary posts 718 are coupled to the spreader member 716 and are substantially parallel to one another. Each of the primary posts 718 is adapted to be coupled to one of the ground-based support connectors 118a of the interface mounting devices 114. The primary posts 718 can each be coupled to the spreader member 716 at various positions so that they are aligned with the ground-based support connectors 118a. Each primary post 718 is also coupled to, and is substantially perpendicular to, an auxiliary post 720. In such embodiments, rather than having the primary posts 718 coupled to the ground-based support connectors 118a, the auxiliary posts 720 can be coupled to the ground-based support connectors 118a, thereby effectively rotating the support structure 710 by 90 degrees relative to the anchoring mechanism 110. Such embodiments advantageously provide adjustability for processing various configurations of structures and to permit alternative configurations best suited for particular applications.

Suspension-Based Support System

[0111] Alternatively, the apparatus 50 can be utilized with a suspension-based support system 800 which is releasably coupled to the apparatus 50. The interface mounting devices 114 can each comprise at least one suspension-based support connector 118b adapted to releasably couple to the suspension-based support system 800. The suspension-based support system 800 advantageously supports some of the weight of the apparatus 50, thereby reducing the weight load supported by the anchoring mechanism 110. The suspension-based support system 800 can be used to facilitate use of the apparatus 50 on substantially vertical surfaces (e.g., outside walls).

[0112] In certain embodiments, as schematically illustrated in Figure 14A, the suspension-based support system 800 comprises a winch 810, a primary cable 812, and a pair of secondary cables 814. The winch 810 is positioned on the roof or other portion of a structure to be processed. The winch 810 is coupled to the primary cable 812, which is coupled to the secondary cables 814. The secondary cables 814 are each coupled to a suspension-based support connector 118b of the interface mounting device 114 of the

anchoring mechanism 110. Figure 14B schematically illustrates one embodiment of the apparatus having the suspension-based support connectors 118b. The apparatus 50 can then be lowered or raised by utilizing the winch 810 to shorten or lengthen the working length of the primary cable 814. In alternative embodiments, the ground-based support connectors 118a can be configured to serve also as the suspension-based support connectors 118b.

Controller

[0113] The controller 500 is electrically coupled to the laser base unit 300 and to the laser manipulation system 100, and is adapted to transmit control signals to the laser base unit 300 and to the laser manipulation system 100. Figure 15 schematically illustrates an embodiment of a controller 500 in accordance with embodiments described herein. The controller 500 comprises a control panel 510, a microprocessor 520, a laser generator interface 530, a positioning system interface 540, a sensor interface 550, and a user interface 560.

[0114] In certain embodiments, the control panel 510 includes a main power supply, main power switch, emergency power off switch, and various electrical connectors adapted to couple to other components of the controller 500. The control panel 510 is adapted to be coupled to an external power source (not shown in Figure 15) and to provide power to various components of the apparatus 50.

[0115] In certain embodiments, the microprocessor 520 can comprise a Programmable Logic Controller microprocessor (PLC). PLCs are rugged, reliable, and easy-to-configure, and exemplary PLCs are available from Rockwell Automation of Milwaukee, Wisconsin, Schneider Electric of Palatine, Illinois, and Siemens AG of Munich, Germany. In alternative embodiments, the microprocessor 520 comprises a personal computer microprocessor, or PC/104 embedded PC modules which provide easy and flexible implementation. The microprocessor 520 can be adapted to respond to input signals from the user (via the user interface 560), as well as from various sensors of the apparatus 50 (via the sensor interface 550), by transmitting control signals to the other components of the apparatus 50 (via the laser generator interface 530 and the positioning system interface 540) to achieve the desired cutting or drilling pattern.

[0116] The microprocessor 520 can be implemented in hardware, software, or a combination of the two. When implemented in a combination of hardware and software, the software can reside on a processor-readable storage medium. In addition, the microprocessor 520 of certain embodiments comprises memory to hold information used during operation.

[0117] In certain embodiments, the laser generator interface 530 is coupled to the laser base unit 300 and is adapted to transmit control signals from the microprocessor 520 to various components of the laser base unit 300. For example, the laser generator interface 530 can transmit control signals to the laser generator 310 to set desired operational parameters, including, but not limited to, laser power output levels and laser pulse profiles and timing. In addition, the laser generator interface 530 can transmit control signals to the cooling subsystem 320 to set appropriate cooling levels, the source of compressed gas coupled to the compressed gas inlet 249 of the containment plenum 240, or to the vacuum generator coupled to the extraction port 248.

[0118] In certain embodiments, the positioning system interface 540 is coupled to the positioning mechanism 121 of the laser manipulation system 100 and is compatible with the first-axis position system 130 and second-axis position system 150, as described above. In certain such embodiments, the positioning system interface 540 comprises servo-drivers for the first-axis position system 130 and the second-axis position system 150. The servo-drivers are preferably responsive to control signals from the microprocessor 520 to generate driving voltages and currents for the first drive 136 and the second drive 154. In this way, the controller 500 can determine how the laser head 200 is scanned across the surface of the structure. In certain embodiments, the servo-drivers receive their power from the control panel 510 of the controller 500. In embodiments in which the positioning mechanism 121 further comprises a third-axis position system, the positioning system interface 540 further comprises an appropriate servo-driver so that the controller 500 can determine the relative distance between the laser head 200 and the structure surface being processed.

[0119] In certain embodiments, the sensor interface 550 is coupled to various sensors (not shown in Figure 15) of the apparatus 50 which provide data upon which operation parameters can be selected or modified. For example, as described above, the laser head 200 can comprise a sensor 250 adapted to measure the relative distance between the

laser head 200 and the interaction region. The sensor interface 550 of such embodiments receives data from the sensor 250 and provide this data to the microprocessor 520. The microprocessor 520 can then adjust various operational parameters of the laser base unit 300 and/or the laser manipulation system 100, as appropriate, in real-time. Other sensors which can be coupled to the controller 500 via the sensor interface 550 include, but are not limited to, proximity sensors to confirm that the laser head 200 is in position relative to the surface being processed, temperature or flow sensors for the various cooling, compressed air, and vacuum systems, and rebar detectors (as described more fully below).

[0120] In certain embodiments, the user interface 560 adapted to provide information regarding the apparatus 50 to the user and to receive user input which is transmitted to the microprocessor 520. In certain embodiments, the user interface 560 comprises a control pendant 570 which is electrically coupled to the microprocessor 520. As schematically illustrated in Figure 16, in certain embodiments, the control pendant 570 comprises a screen 572 and a plurality of buttons 574.

[0121] The screen 572 can be used to display status information and operational parameter information to the user. Exemplary screens 572 include, but are not limited to, liquid-crystal displays. The buttons 574 can be used to allow a user to input data which is used by the microprocessor 520 to set operational parameters of the apparatus 50. Other embodiments can use other technologies for communicating user input to the apparatus 50, including, but not limited to, keyboard, mouse, touchpad, and potentiometer knobs and/or dials. In certain embodiments, the control pendant 570 is hard-wired to the apparatus 50, while in other embodiments, the control pendant 570 communicates remotely (e.g., wirelessly) with the apparatus 50.

[0122] In certain embodiments, the control pendant 570 further comprises an emergency stop button and a cycle stop button. Upon pressing the emergency stop button, the apparatus 50 immediately ceases all movement and the laser irradiation is immediately halted. Upon pressing the cycle stop button, the apparatus 50 similarly ceases all movement and halts laser irradiation corresponding to the cutting sequence being performed, but the user is then provided with the option to return to the beginning of the cutting sequence or to re-start cutting at the spot where the cutting sequence was stopped. In certain embodiments,

the control pendant 570 further comprises a “dead man switch,” which must be manually actuated by the user for the apparatus 50 to perform. Such a switch provides a measure of safety by ensuring that the apparatus 50 is not run without someone actively using the control pendant 570.

[0123] Figures 17A-17H illustrate a set of exemplary screen displays of the control pendant 570. The function of each of the buttons 574 along the left and right sides of the screen 572 is dependent on the operation mode of the apparatus 50. Each of the screen displays provides information regarding system status along with relevant information regarding the current operation mode.

[0124] The “MAIN SCREEN” display of Figure 17A comprises a “Machine Status” field, a “System Status” field, and label fields corresponding to the functions of some or all of the buttons 574 of the control pendant 570. The “Machine Status” field includes a text message which describes what the apparatus 50 is doing and what the user may do next. The “System Status” field includes a box which shows the operational mode of the apparatus 50. In the example illustrated by Figure 17A, the apparatus is in “maintenance mode.” The “System Status” field also includes a plurality of status boxes which indicate the status of various components of the apparatus 50, including, but not limited to, the vacuum pads 112 of the anchoring system 110, the air or vacuum pressure, the first-axis position system 130, and the second-axis position system 150. The “System Status” field also indicates whether there are any faults sensed with the laser base unit 300. In certain embodiments, nominal status of a component is shown with the corresponding status box as green. The ready state of the apparatus 50 is illustrated by having all the system status boxes appear as green. If the status of one of these components is outside operational parameters, the corresponding status box is shown as red, and the system interlocks are enabled, preventing operation of the apparatus 50. Upon startup, the system interlocks are enabled and must be cleared prior to operation of the apparatus 50. The text messages of the “Machine Status” field provide information regarding the actions to be performed to place the apparatus 50 within operational parameters and to clear the system interlocks. Upon clearing all the system interlocks, the “Machine Status” field will indicate that the apparatus 50 is ready to be used.

[0125] The “SELECT OPERATION SCREEN” display of Figure 17B comprises the “Machine Status” field, the “System Status” field, and the label fields corresponding to the functions of some or all of the buttons 574. The “System Status” field includes information regarding the position of the laser head 200 along the first-axis position system 130 (referred to as the long axis) and the second-axis position system 150 (referred to as the short axis). Some of the buttons 574 are configured to enable various operations. For example, four buttons 574 are configured to enable four different operations: circle, pierce, straight cut, and surface keying, as illustrated in Figure 17B.

[0126] Figure 17C shows a “CIRCLE SETUP/OPERATION SCREEN” display which provides information regarding the circle operation of the apparatus 50 in which the laser head 200 moves circularly to cut a circular pattern to a desired depth into the surface of the structure to be processed. In certain embodiments, the circle operation can be used for “trepanning,” whereby a solid circular core is cut and removed from the surface, leaving a circular hole.

[0127] A “Circle Status” field provides information regarding the status of the circle operation and corresponding instructions to the user. The starting position of the laser head 200 along the first-axis position system 130 and the second-axis position system 150 are provided in the “System Status” field. A “Circle Parameters” field provides information regarding various parameters associated with the cutting of a circular pattern, including, but not limited to, the number of revolutions around the circular pattern, the diameter, time period that the cutting will be performed, the speed of motion of the laser head 200 around the circle, and the laser base unit (LBU) program number. In certain embodiments, the LBU program number corresponds to operational parameters of the laser head 200 including, but not limited to, beam focus and intensity.

[0128] In certain embodiments, the various parameters can be changed by touching the parameter on the screen 572, upon which a numerical keypad will pop up on the screen 572 so that a new value can be entered. For each parameter, the “set point” value corresponds to the value currently in memory and the last value that was entered. The “status” value corresponds to the current value being selected. Upon saving the new parameter value, the “status” and “set point” values are the same. Pressing the button 574a

labeled “Auto/Dry Run” will initiate the circular movement of the laser head 200 without activating the laser beam, to ensure the desired motion. Pressing the button 574b labeled “Cycle Start” will initiate the cutting of the circular pattern, including both the movement of the laser head 200 and the activation of the laser beam. Pressing the button 574c labeled “Cycle Stop” will halt or pause the cutting and movement, with the option to re-start the cutting and movement where it was halted. Pressing the button 574d labeled “Machine Reset” will place the apparatus 50 in a neutral condition. Pressing the button 574e labeled “Next” upon completion of the cutting will return to the “SELECT OPERATION SCREEN.”

[0129] Figure 17D shows a “PIERCE SETUP/OPERATION SCREEN” display which provides information regarding the pierce operation of the apparatus 50 in which the laser head 200 drills a hole to a desired depth into the surface of the structure to be processed. A “Pierce Status” field provides information regarding the status of the pierce operation and corresponding instructions to the user. The starting position of the laser head 200 along the first-axis position system 130 and the second-axis position system 150 are provided in the “System Status” field. A “Pierce Parameters” field provides information regarding various parameters associated with the drilling of a hole. The laser parameters can include, but are not limited to, the laser power, the laser spot size, and the time period for drilling (each of which can influence the diameter of the resultant hole which is formed in the structure), and the LBU program number. The parameters can be changed as described above. The buttons 574 labeled “Auto/Dry Run,” “Cycle Start,” “Cycle Stop,” “Machine Reset,” and “Next” operate as described above.

[0130] Figure 17E shows a “CUT SETUP/OPERATION SCREEN” display which provides information regarding the straight cutting operation of the apparatus 50 in which the laser head 200 makes a straight cut to a desired depth in the surface of the structure to be processed. The straight cut is preferably along one of the axes of the apparatus 50. A “Cut Status” field provides information regarding the status of the cut operation and corresponding instructions to the user. The starting position of the laser head 200 along the first-axis position system 130 and the second-axis position system 150 are provided in the “System Status” field. A “Cut Parameters” field provides information regarding various parameters associated with the cutting, including, but not limited to, the speed of motion of

the laser head 200, the length of the cut to be made, and the LBU program number. The parameters can be changed as described above. The buttons 574f, 574g labeled “Long Axis” and “Short Axis” are used to select either the first axis or the second axis respectively as the axis of motion of the laser head 200. The buttons 574 labeled “Auto/Dry Run,” “Cycle Start,” “Cycle Stop,” “Machine Reset,” and “Next” operate as described above.

[0131] Figure 17F shows a “SURFACE KEYING SETUP/OPERATION SCREEN” display which provides information regarding the surface keying operation of the apparatus 50 in which the laser head 200 cuts an indentation or key into the surface of the structure to be processed. The surface keying operation includes scanning the laser beam across the surface to create an indentation or “key” in the surface with a desired depth and with a generally rectangular area. In certain embodiments, the surface keying operation can be used to perform “scabbling” of the surface, whereby the surface is roughened by interaction with the laser beam across an area (e.g., rectangular).

[0132] A “Surface Keying Status” field provides information regarding the status of the surface keying operation and corresponding instructions to the user. The starting position of the laser head 200 along the first-axis position system 130 and the second-axis position system 150 are provided in the “System Status” field. A “Surface Keying Parameters” field provides information regarding various parameters associated with the cutting, including, but not limited to, the speed of motion of the laser head 200, the length of the key to be made along the first axis and along the second axis, the offset length that the apparatus 50 will increment between movement along the first axis and the second axis, and the LBU program number. The parameters can be changed as described above. The buttons 574f, 574g labeled “Long Axis” and “Short Axis” are used to select either the first axis or the second axis respectively as the axis of motion of the laser head 200. The buttons 574 labeled “Auto/Dry Run,” “Cycle Start,” “Cycle Stop,” “Machine Reset,” and “Next” operate as described above.

[0133] Figure 17G shows a “FAULT SCREEN” display which provides information regarding detected operation faults. A fault occurs when a sensor (e.g., flowmeters, temperature sensors, safety switches, emergencies stops) of the monitored systems detects a non-operational condition, and can occur while the apparatus 50 is any of

the operational modes and while any of the screens are being displayed. When a fault occurs, a scrolling message indicating the fault is preferably provided at the bottom of the current screen being displayed. In addition, the “Machine Status” field will indicate to the user to clear the faults. The “FAULT SCREEN” can be accessed from any of the other screens by pressing an appropriate button 574. As illustrated in Figure 17G, in certain embodiments, the “FAULT SCREEN” displays the detected faults in a table with the relevant data, including, but not limited to, the date and the type of fault. To prepare the apparatus 50 for operation, the detected faults are preferably cleared by the user. After clearing the detected faults, the user can press an appropriate button 574 (e.g., “Acknowledge All”) to acknowledge the faults. If the faults are not cleared, the user can press an appropriate button 574 (e.g., “Machine Reset”) to return to the screen being displayed when the fault occurred. Pressing the “Machine Reset” button 574 again will return the user to the “MAIN SCREEN” from where the apparatus 50 can be reset.

[0134] Figure 17H shows a “MAINTENANCE SCREEN” display which provides information regarding the apparatus 50. The maintenance mode can be accessed from the “MAIN SCREEN” display by pressing an appropriate button 574. In the maintenance mode, the system interlocks are bypassed, therefore the user preferably practices particular care to avoid damaging the apparatus 50 or people or materials in proximity to the apparatus 50. The “MAINTENANCE SCREEN” can display an appropriate warning to the user.

[0135] The maintenance mode provides an opportunity for the user to check the operation of various components of the apparatus 50 independent of the fault status of the apparatus 50. For example, by pressing appropriate buttons 574 in the maintenance mode, the vacuum system can be turned on and off, the compressed air can be turned on and off via a solenoid valve, and the first drive 136 and second drive 154 can be turned on and off. In addition, the default jog speed of the first axis and second axis can be changed by pressing the screen 572 to pop up a numerical keypad display, as described above.

[0136] The “System Status” field also includes a plurality of status boxes which indicate the status of various components of the apparatus 50, including, but not limited to, the vacuum pads 112 of the anchoring system 110, the air or vacuum pressure, the first-axis

position system 130, and the second-axis position system 150. The “System Status” field also indicates whether there are any faults sensed with the laser base unit 300. In certain embodiments, nominal status of a component is shown with the corresponding status box as green. The ready state of the apparatus 50 is illustrated by having all the system status boxes appear as green. If the status of one of these components is outside operational parameters, the corresponding status box is shown as red.

[0137] The “MAINTENANCE SCREEN” can also provide the capability to move the laser head 200 along the first axis and second axis, as desired. A set of three buttons 574 are configured to move the laser head 200 along the first axis to a home position, in a forward direction, or in a backward direction, respectively. Similarly, another set of three buttons 574 are configured for similar movement of the laser head 200 along the second axis. The label field for these sets of buttons can include information regarding the position of the laser head 200 along these two axes.

Detector

[0138] In certain embodiments, the controller 500 is coupled to a detector 600 adapted to detect embedded material in the structure while processing the structure, and to transmit detection signals to the controller 500. In certain embodiments, the controller 500 is adapted to avoid substantially damaging the embedded material by transmitting appropriate control signals to the laser base unit 300 and the laser manipulation system 100. In certain embodiments, the detector 600 is adapted to utilize light emitted by the interaction region during processing to detect embedded material.

[0139] Various technologies for detecting embedded material are compatible with embodiments of the present invention. Spectral analysis of the light emitted by the interaction region during processing can provide information regarding the chemical constituents of the material in the interaction region. By analyzing the wavelength and intensity of the light, it is possible to determine the composition of the material being heated and its temperature. Using spectroscopic information, the detection of embedded materials in certain embodiments relies on monitoring changes in the light spectrum during processing. With the differences in composition of embedded materials, by way of example and not limitation, such as rebar (e.g., steel) embedded in concrete, variations in the melting and

boiling temperatures for the diverse materials will produce noticeable changes in the amount of light, and/or the wavelength of the light when the laser light impinges and heats the embedded material.

[0140] Figure 18 schematically illustrates a detector 600 compatible with embodiments described herein. The detector 600 comprises a focusing lens 610, an optical fiber 620, and a spectrometer 630. The spectrometer 630 of certain embodiments comprises an optical grating 632 and a light sensor 634. In certain embodiments, the spectrometer 630 also comprises a microprocessor to analyze the resulting spectroscopic data. In other embodiments, the spectrometer 630 is coupled to such a microprocessor. The focusing lens 610 is positioned to receive light emitted from the interaction region, which is directed onto the optical fiber 620. The optical fiber 620 then delivers the light to the spectrometer 630, and the optical grating 632 of the spectrometer 630 separates the light into a spectrum of wavelengths. The separated light having a selected range of wavelengths can then be directed onto the light sensor 634 which generates a signal corresponding to the intensity of the light in the range of wavelengths. The spectrometer 630 can monitor specific wavelengths that are associated with various embedded materials in the structure. In certain embodiments, the spectrometer 630 can monitor the relative intensity of the light at, or in spectral regions in proximity to, these wavelengths. Additionally, at least one neutral density filter may be employed to decrease the light reaching the spectrometer 630 to improve spectral analysis performance.

[0141] In certain embodiments, at least a portion of the detector 600 is mounted onto the laser head 200. In embodiments in which the focusing lens 610 is part of the laser head 200, the focusing lens 610 can be positioned close to the axis of the emitted laser light so as to receive light from the interaction region. In such embodiments, the focusing lens 610 can be behind the nozzle 244 and protected by the compressed air from the compressed air inlet 249, as is the window 243. In certain embodiments, the focusing lens 610 is coaxial with the laser beam, while in other embodiments, the focusing lens 610 is located off-axis.

[0142] Exemplary focusing lenses 610 include, but are not limited to, UV-74 from Ocean Optics of Dunedin, Florida. Exemplary optical fibers 620 include, but are not limited to, P400-2-UV/VIS from Ocean Optics of Dunedin, Florida. Exemplary

spectrometers 630 include, but are not limited to, USB2000(VIS/UV) from Ocean Optics of Dunedin, Florida.

[0143] In certain embodiments, the spectrometer 630 monitors the intensity at a specific wavelength and the intensities on both sides of this wavelength. The spectrometer 630 of certain embodiments also monitors the reduction of the intensities resulting from the increased depth of the hole being drilled. Figure 19 shows an exemplary graph of the light spectrum detected upon irradiating concrete with laser light and the light spectrum detected upon irradiating an embedded rebar. The spectrum from concrete shows an emission peak at a wavelength of approximately 592 nanometers. The spectrum from rebar does not have this emission peak, but instead shows an absorption dip at approximately the same wavelength. Thus, the emission spectrum at about 592 nanometers can be used to provide a real-time indication of whether an embedded rebar is being cut by the laser light. For example, by sampling the emission spectrum at about 588.5 nanometers, 592 nanometers, and 593 nanometers, and calculating the ratio: $(2 \times I_{592}) / (I_{593} + I_{588.5})$, the detector 600 can determine whether the emission spectrum has a dip corresponding to concrete or a peak corresponding to embedded rebar. Other spectroscopic data can be used in other embodiments.

[0144] An alternative technology for detecting embedded materials uses high speed shutter monitoring. This approach utilizes advances in Coupled Capacitance Discharge (CCD) camera systems to monitor discrete changes in the interactions between the material to be processed and the laser light. Newer CCD cameras have systems that can decrease the time the shutter is open to about 0.0001 second. At this speed, it is possible to see many features of the interaction between the laser light and the material being processed. Additionally, neutral density filters may be employed to decrease the glare observed from the incandescent interaction of the laser light and the material to be processed and to better image the interaction region.

[0145] Numerous alterations, modifications, and variations of the various embodiments disclosed herein will be apparent to those skilled in the art and they are all anticipated and contemplated to be within the spirit and scope of the instant invention. For example, although specific embodiments have been described in detail, those with skill in the art will understand that the preceding embodiments and variations can be modified to

incorporate various types of substitute and/or additional or alternative materials, relative arrangement of elements, and dimensional configurations. Accordingly, even though only few variations of the present invention are described herein, it is to be understood that the practice of such additional modifications and variations and the equivalents thereof, are within the spirit and scope of the invention as defined in the following claims.

[0146] The corresponding structures, materials, acts, and equivalents of all means or step plus function elements in the claims below are intended to include any structure, material, or acts for performing the functions in combination with other claimed elements as specifically claimed.
